# Database Management System

## Introduction to SQL

Lecture-08

Date: 27 Jan 2023

Dr. Sumit Sharma  
Assistant Professor

Computer Science and Engineering Department  
Thapar Institute of Engineering and Technology, Patiala

# Recap

- Overview of The SQL Query Language
- SQL Data Definition
- Basic Query Structure of SQL Queries
- Basic Operations

# Basic Query Structure

- A typical SQL query has the form:

**select**  $A_1, A_2, \dots, A_n$   
**from**  $r_1, r_2, \dots, r_m$   
**where**  $P$

- $A_i$  represents an attribute
  - $R_i$  represents a relation
  - $P$  is a predicate.
- The result of an SQL query is a relation.

# The Select Clause

- The **select** clause lists the attributes desired in the result of a query
  - corresponds to the **projection operation** of the relational algebra
- Example: find the names of all instructors:  
**select** *name*  
**from** *instructor*
- NOTE: SQL names are case insensitive (i.e., you may use upper- or lower-case letters.)
  - E.g., *Name*  $\equiv$  *NAME*  $\equiv$  *name*
  - Some people use upper case wherever we use bold font.

# The Select Clause

- SQL allows duplicates in relations as well as in query results.
- To force the **elimination of duplicates**, insert the keyword **distinct** after select.
- Find the department names of all instructors, and remove duplicates

```
select distinct dept_name  
from instructor
```

- The keyword specifies that duplicates should not be removed.

```
select all dept_name  
from instructor
```

- An asterisk in the select clause denotes “all attributes”

```
select *  
from instructor
```

| <i>dept_name</i> |
|------------------|
| Comp. Sci.       |
| Finance          |
| Music            |
| Physics          |
| History          |
| Physics          |
| Comp. Sci.       |
| History          |
| Finance          |
| Biology          |
| Comp. Sci.       |
| Elec. Eng.       |

# The Select Clause

- An asterisk in the select clause denotes “all attributes”

**select \***  
**from instructor**

- An attribute can be a literal with no from clause

**select '437'**

- Results is a table with one column and a single row with value “437”
- Can give the column a name using:

**select '437' as FOO**

- An attribute can be a literal with from clause

**select 'A'**  
**from instructor**

- Result is a table with one column and N rows (number of tuples in the instructors table), each row with value “A”

# The Select Clause

- The **select** clause can contain arithmetic expressions involving the operation, +, −, \*, and /, and operating on constants or attributes of tuples.

- The query:

```
select ID, name, salary/12  
from instructor
```

would return a relation that is the same as the *instructor* relation, except that the value of the attribute *salary* is divided by 12.

- Can rename “salary/12” using the **as** clause:

```
select ID, name, salary/12 as monthly_salary
```

# The where clause

- The **where** clause specifies conditions that the result must satisfy
  - Corresponds to the selection predicate of the relational algebra.
- To find all instructors in Comp. Sci. dept

```
select name  
from instructor  
where dept_name = 'Comp. Sci.'
```

- SQL allows the use of the logical connectives **and**, **or**, and **not**
- The operands of the logical connectives can be expressions involving the comparison operators **<**, **<=**, **>**, **>=**, **=**, and **<>**.
- Comparisons can be applied to results of arithmetic expressions
- To find all instructors in Comp. Sci. dept with salary > 70000

```
select name  
from instructor  
where dept_name = 'Comp. Sci.' and salary > 70000
```

| <i>name</i> |
|-------------|
| Katz        |
| Brandt      |

# The from Clause

- The **from** clause lists the relations involved in the query
  - Corresponds to the **Cartesian product** operation of the **relational algebra**.
- Find the Cartesian product *instructor X teaches*  
**select \***  
**from *instructor, teaches***
  - generates every possible instructor – teaches pair, with all attributes from both relations.
  - For common attributes (e.g., *ID*), the attributes in the resulting table are renamed using the relation name (e.g., *instructor.ID*)
- Cartesian product not very useful directly, but useful combined with where-clause condition (selection operation in relational algebra).

# Cartesian Product of instructor and teaches table

| <i>instructor.ID</i> | <i>name</i> | <i>dept_name</i> | <i>salary</i> | <i>teaches.ID</i> | <i>course_id</i> | <i>sec_id</i> | <i>semester</i> | <i>year</i> |

# Natural Join

- Find the names of all instructors who have taught some course and the course\_id

```
select name, course_id  
from instructor , teaches  
where instructor.ID = teaches.ID
```

- Can be written more concisely using natural join

```
select name, course id  
from instructor natural join teaches;
```

| <i>name</i> | <i>course_id</i> |

# The Rename Operation

- The SQL allows renaming relations and attributes using the **as** clause:

*old-name as new-name*

- Find the names of all instructors who have a higher salary than some instructor in 'Comp. Sci'.

- **select distinct** *T.name*  
**from** *instructor as T, instructor as S*  
**where** *T.salary > S.salary and S.dept\_name = 'Comp. Sci.'*

- Keyword **as** is optional and may be omitted

*instructor as T*  $\equiv$  *instructor T*

# String Operations

- SQL includes a string-matching operator for comparisons on character strings. The operator **like** uses patterns that are described using two special characters:
  - percent ( % ). The % character matches any substring.
  - underscore ( \_ ). The \_ character matches any character.
- Find the names of all instructors whose name includes the substring “dar”.

```
select name  
from instructor  
where name like '%dar%'
```

- Match the string “100%”

```
like '100 \%' escape '\'
```

in that above we use backslash (\) as the escape character.

# String Operations

- Patterns are case sensitive.
- Pattern matching examples:
  - 'Intro%' matches any string beginning with “Intro”.
  - '%Comp%' matches any string containing “Comp” as a substring.
  - '\_\_\_' matches any string of exactly three characters.
  - '\_\_\_ %' matches any string of at least three characters.
- SQL supports a variety of string operations such as
  - concatenation (using “||”)
  - converting from upper to lower case (and vice versa)
  - finding string length, extracting substrings, etc.

# Ordering the Display of Tuples

- List in alphabetic order the names of all instructors

```
select distinct name  
from instructor  
order by name
```

- We may specify **desc** for descending order or **asc** for ascending order, for each attribute; ascending order is the default.
  - Example: **order by** *name* **desc**
- Can sort on multiple attributes
  - Example: **order by** *dept\_name* **desc**, *name* **asc**

# Where Clause Predicates

- SQL includes a **between** comparison operator
- Example: Find the names of all instructors with salaries between \$90,000 and \$100,000 (that is,  $\geq \$90,000$  and  $\leq \$100,000$ )
  - ***select name***  
***from instructor***  
***where salary between 90000 and 100000***
- Tuple comparison
  - ***select name, course\_id***  
***from instructor, teaches***  
***where (instructor.ID, dept\_name) = (teaches.ID, 'Biology');***

# Set Operations

- Find courses that ran in Fall 2017 or in Spring 2018

```
(select course_id from section where sem = 'Fall' and year = 2017)  
union  
(select course_id from section where sem = 'Spring' and year = 2018)
```

- Find courses that ran in Fall 2017 and in Spring 2018

```
(select course_id from section where sem = 'Fall' and year = 2017)  
intersect  
(select course_id from section where sem = 'Spring' and year = 2018)
```

- Find courses that ran in Fall 2017 but not in Spring 2018

```
(select course_id from section where sem = 'Fall' and year = 2017)  
except  
(select course_id from section where sem = 'Spring' and year = 2018)
```

# Set Operations

- Set operations **union**, **intersect**, and **except**
  - Each of the above operations automatically eliminates duplicates
- To retain all duplicates use the
  - **union all**
  - **intersect all**
  - **except all**

# Null Values

- It is possible for tuples to have a null value, denoted by **null**, for some of their attributes
- **null** signifies an unknown value or that a value does not exist.
- The result of any arithmetic expression involving **null** is **null**
  - Example:  $5 + \text{null}$  returns **null**
- The predicate **is null** can be used to check for null values.
  - Example: Find all instructors whose salary is null.

```
select name  
from instructor  
where salary is null
```

- The predicate **is not null** succeeds if the value on which it is applied is not null.

# Null Values

- SQL treats as **unknown** the result of any comparison involving a null value (other than predicates **is null** and **is not null**).
  - Example:  $5 < \text{null}$  or  $\text{null} <> \text{null}$  or  $\text{null} = \text{null}$
- The predicate in a **where** clause can involve Boolean operations (**and**, **or**, **not**); thus the definitions of the Boolean operations need to be extended to deal with the value **unknown**
  - **and** :  $(\text{true and unknown}) = \text{unknown}$ ,  
 $(\text{false and unknown}) = \text{false}$ ,  
 $(\text{unknown and unknown}) = \text{unknown}$
  - **or**:  $(\text{unknown or true}) = \text{true}$ ,  
 $(\text{unknown or false}) = \text{unknown}$   
 $(\text{unknown or unknown}) = \text{unknown}$
- Result of **where** clause predicate is treated as *false* if it evaluates to *unknown*

# Aggregate Functions

- These functions operate on the multiset of values of a column of a relation, and return a value

**avg:** average value

**min:** minimum value

**max:** maximum value

**sum:** sum of values

**count:** number of values

# Aggregate Functions Example

- Find the average salary of instructors in the Computer Science department
  - **select avg** (*salary*)  
**from** *instructor*  
**where** *dept\_name*= 'Comp. Sci.';
- Find the total number of instructors who teach a course in the Spring 2018 semester
  - **select count** (**distinct** *ID*)  
**from** *teaches*  
**where** *semester* = 'Spring' **and** *year* = 2018;
- Find the number of tuples in the *course* relation
  - **select count** (\*)  
**from** *course*;

# Aggregate Functions – Group By

- Find the average salary of instructors in each department
  - select** *dept\_name*, **avg** (*salary*) **as** *avg\_salary*  
**from** *instructor*  
**group by** *dept\_name*;

| <i>ID</i> | <i>name</i> | <i>dept_name</i> | <i>salary</i> |
|-----------|-------------|------------------|---------------|
| 76766     | Crick       | Biology          | 72000         |
| 45565     | Katz        | Comp. Sci.       | 75000         |

| 22222     | Einstein    | Physics          | 95000         |

| <i>dept_name</i> | <i>avg_salary</i> |
|------------------|-------------------|
| Biology          | 72000             |
| Comp. Sci.       | 77333             |
| Elec. Eng.       | 80000             |
| Finance          | 85000             |
| History          | 61000             |
| Music            | 40000             |
| Physics          | 91000             |

# Aggregate Functions – Having Clause

- Find the names and average salaries of all departments whose average salary is greater than 42000

```
select dept_name, avg (salary) as avg_salary  
from instructor  
group by dept_name  
having avg (salary) > 42000;
```

- Note: predicates in the **having** clause are applied **after** the formation of groups whereas predicates in the **where** clause are applied **before** forming groups

**Thanks!**
